How does an inverter lose power?

However there are limits in power, voltage and current. When attaining one of these limits, the inverter will clip the operating point on the intersection of the I/V curve and this limit. The power difference between the MPP of the arrays' I/V curve and the effective power of this operating point on the limit curves is accounted as inverter loss:

What are the parameters of an inverter?

The main basic parameter of the inverter is the Nominal AC power P_{nom} , that is the maximum power the inverter is able to deliver to the grid in any conditions. Some manufacturers specify also a Maximum AC power P_{max} , as a power which may be attained in specific conditions.

How does an inverter track a power point?

In normal conditions it will choose the maximum power point (MPPT tracking). However there are limits in power, voltage and current. When attaining one of these limits, the inverter will clip the operating point on the intersection of the I/V curve and this limit.

What are the key features of an inverter?

Key features of inverters: Power factor (pf) setting: The power factor ($\cos(\phi)$) defines the ratio of active to reactive power at both the inverter outputs and the grid connection point. Power grid limitation: Grid operators may impose a limit on the inverter's active power output to manage the amount of power injected into the grid.
